1 Series

The kernel matrix in Williams & Porter (2009) is $i = \sqrt{-1}$ multiplied by the following:

$$G_{mn}^{(j)} = \sum_{\alpha \in \mathscr{S}_j} B_j^{(2)}(\alpha) F_m^{(j)}(\alpha) F_n^{(j)}(\alpha). \tag{1}$$

In practice we truncate this series so there are only N imaginary roots in $\mathscr{S}_j$, i.e.

$$G_{mn}^{(j)}(N) = \sum_{\alpha \in \mathscr{S}_j^{(N)}} B_j^{(2)}(\alpha) F_m^{(j)}(\alpha) F_n^{(j)}(\alpha), \tag{2}$$

where $\mathscr{S}_j^{(N)} \subset \mathscr{S}_j$.

$$
\begin{aligned}
F_n^{(j)}(\alpha) &= \frac{2}{H_1} \int_{-H}^{-\sigma_1} \varphi^{(j)}(z, \alpha) \mathscr{C}_{2n}\left(\frac{z+H}{H_1}\right) dz \\
&= 2\operatorname{sech}(\gamma H_j) \int_0^1 \cos(\kappa t) \mathscr{C}_{2n}(t) dt \\
&= \frac{(-1)^n \Gamma(\beta)}{\cosh(\gamma H_j)} \left(\frac{\kappa}{2}\right)^{-\beta} (2n+\beta) J_{2n+\beta}(\kappa),
\end{aligned}
\tag{3}
$$

where $\kappa = -i\gamma H_2$.

Now let $\tilde{\gamma}_{j,r} = in\pi/H_j$, and $\tilde{\kappa}_{j,r} = -i\tilde{\gamma}_{j,r} H_2 = r\pi H_2/H_j = r\pi/\hat{H}_j$ ($r = 1, 2, \ldots$). Then

$$B_j^{(2)}(\tilde{\gamma}_{j,r}) = \frac{i}{r\pi}, \tag{4a}$$

$$
\begin{aligned}
J_{2n+\beta}(\tilde{\kappa}_{j,r}) &= \sqrt{\frac{2}{\pi\tilde{\kappa}_{j,r}}} \cos\left(\tilde{\kappa}_{j,r} - (2n+\beta)\frac{\pi}{2} - \frac{\pi}{4}\right) \\
&= (-1)^n r^{-1/2} \sqrt{\frac{2\hat{H}_j}{\pi^2}} \cos\left(\tilde{\kappa}_{j,r} - \beta'\right),
\end{aligned}
\tag{4b}
$$

$$\beta' = \frac{\pi}{2}\left(\beta + \frac{1}{2}\right). \tag{4c}$$

Thus

$$F_n^{(j)}(\tilde{\gamma}_{j,r}) = (-1)^r r^{-(2\beta+1)/2} f_{j,n}(\beta) \cos(\tilde{\kappa}_{j,r} - \beta'),\tag{5a}$$

$$f_{j,n}(\beta) = \Gamma(\beta)(2n+\beta)\left(\frac{\pi}{2\hat{H}_j}\right)^{-\beta}\sqrt{\frac{2\hat{H}_j}{\pi^2}},\tag{5b}$$

and

$$\tilde{G}_{mn}^{(j)}(N) = \sum_{r=1}^{N} B_j^{(2)}(\tilde{\gamma}_{j,r}) F_m^{(j)}(\tilde{\gamma}_{j,r}) F_n^{(j)}(\tilde{\gamma}_{j,r})$$

$$= \frac{i}{\pi} f_{j,n}(\beta) f_{j,m}(\beta) \sum_{r=1}^{N} r^{-s} \cos^2(\tilde{\kappa}_{j,r} - \beta').\tag{6}$$

where $s = 2(\beta + 1)$. Therefore

$$\tilde{G}_{mn}^{(j)} = \lim_{N\to\infty} \tilde{G}_{mn}^{(j)}(N)$$

$$= \frac{i}{2\pi} f_{j,n}(\beta) f_{j,m}(\beta) \sum_{r=1}^{\infty} r^{-s} \left(1 + \text{Re}\left(e^{-2i\beta'} e^{2i\pi r/\hat{H}_j}\right)\right)$$

$$= \frac{i}{2\pi} f_{j,n}(\beta) f_{j,m}(\beta) \left(\zeta(s) + \text{Re}\left(e^{-2i\beta'} \text{Li}_s\left(e^{2i\pi/\hat{H}_j}\right)\right)\right),\tag{7}$$

where

$$\text{Li}_s(z) = \sum_{r=1}^{\infty} \frac{z^r}{r^s} \quad \text{for } |z| \leq 1 \tag{8}$$

($|z| <= 1$) is the polylogarithm function (Wood, 1992). Note that $\text{Li}_s(1) = \zeta(s)$.
It has the Bose-Einstein integral representation

$$\text{Li}_s(z) = \frac{z}{\Gamma(s)} \int_0^{\infty} \frac{t^{s-1}e^{-t}}{1 - ze^{-t}} dt \quad \text{for } z \in \mathbb{C}\backslash[1, \infty),\tag{9}$$

where Li_s has a branch cut. It converges reasonably well unless z gets too close
to this branch cut. By taking the Mellin transform of this, Wood (1992) derives
the expansion in $w = \log z$ which works extremely well near $z = 1$ ($|w| \leq 2\pi$):

$$\text{Li}_s(e^w) = \sum_{k=0}^{\infty} \zeta(s-k) \frac{w^k}{k!} + \Gamma(1-s)(-w)^{s-1} \quad (s \neq 1, 2, \ldots),\tag{10}$$

or

$$\text{Li}_s(e^w) = \sum_{k=0,\, k\neq s-1}^{\infty} \zeta(s-k) \frac{w^k}{k!} + f_s(w)\frac{w^{s-1}}{(s-1)!} \quad (s = 1, 2, \ldots)\tag{11}$$

where

$$f_s(w) = \sum_{k=1}^{s-1} \frac{1}{k} - \log(-w).$$

2

Near $z = 1$ $(|w| = |\log(-z)| < \pi)$, the alternative series works well:

$$\mathrm{Li}_s(\mathrm{e}^{-w}) = - \sum_{k=0,\, k \neq s-1}^{\infty} \eta(s-k) \frac{w^k}{k!}, \qquad (12)$$

where $\eta(s) = (1 - 2^{1-s})\zeta(s)$. This integral can be done very efficiently with Gauss-Laguerre quadrature. Also, $\mathrm{Li}_s(1) = \zeta(s)$, which implies that for $j = 2$, when $\hat{H}_2 = 1$,

$$\tilde{G}_{mn}^{(2)} = \frac{\mathrm{i}}{2\pi} f_{2,n}(\beta) f_{2,m}(\beta) \zeta(s) \left(1 + \cos(2\beta')\right),$$
$$= \frac{\mathrm{i}}{\pi} f_{2,n}(\beta) f_{2,m}(\beta) \zeta(s) \cos^2(\beta') \qquad (13)$$

Finally we approximate

$$G_{mn}^{(j)} \approx G_{mn}^{(j)}(N) - \tilde{G}_{mn}^{(j)}(N) + \tilde{G}_{mn}^{(j)}, \qquad (14)$$

which gives the summand in the series (6) decays like $O(r^{-(s+1)})$. This means it can be truncated at a much lower value of N.
